TITLE: An investigation of the fine structure of explosion-hardened armco iron

SOURCE: Fizika metallov i metallovedeniye, v. 19, no. 6, 1965, 923-925

TOPIC TAGS: iron, metal hardening, hardness, fine structure, metal stress

ABSTRACT: The relationship between the hardening produced by explosion and the fine-structure characteristics of armco iron containing 0.05% carbon was studied. As the hardness varied, changes were observed in broadening of the x-ray diffraction lines, second-order stresses, dislocation density, and size of mosaic blocks. The data shows that the passage of the elastic-plastic wave during explosive loading is associated with the development of defects in the fine structure. A definite relationship could not be established between the hardening and any of the fine-structure characteristics studied. However, a comparison of the hardening with the broadening of the (220) line shows that the hardening is related to the appearance of at least two types of defects which differ in character or in distri-

TITLE: Effect of twinning and grain size of metal hardening under conditions of explosive stressing

SOURCE: Ref. zh. Metallyrgiya, Abs. 7I257

REF SOURCE: Sb. Materialy Nauchn. konferentsii. Sovnarkhoz Nizhne-Volzhsk. ekon. r-na. Volgogradsk. politekhn. in-t. T. 1. Volgograd, 1965, 269-271

TOPIC TAGS: steel microstructure, metal hardening, grain size, twinning, explosive stress, microhardness/Armco iron

ABSTRACT: An analysis was made of the characteristics of the microstructure of Armco iron subjected to various impact pressures (120 and 200 kbar). At 120 kbar impact pressure, the Brinell hardness is 140 at the surface of impact, and the microstructure shows two types of grains—with twinnings and without. The microhardness of the grains with twinning is higher. The growth of twinnings under explosive stresses promotes the hardening of Fe, and the hardening is intensified in proportion to the size reduction of the initial grain. Preliminary

cold straining lowers the growth of twinning in subsequent explosive which apparently explains the relatively small increase in hardening as a result of explosive stressing of such Me. Additional high hardening of Me under high-speed stressing is explained by the effect of plane defects of the structure, specifically, in the grain boundaries and twinnings. L. Gordienko. TITLE: Softening in annealing of Armco iron subjected to explosive forming

SOURCE: Ref. zh. Metallurgiya, Abs. 71260

REF SOURCE: Sb. Materialy Nauchn. konferentsii. Sovnarkhoz Nizhne-Volzhsk. ekon. r-na. Volgogradsk. politekhn. in-t. T. 1. Volgograd, 1965, 272-274

TOPIC TAGS: metal softening, work hardening, activation energy, recrystallization, explosive forming, annealing, iron/Armco iron

ABSTRACT: To investigate the peculiarities of work hardening of Armco iron subjected to explosive forming the kinetics of rest and recrystallization are investigated and the process activation energy is determined. A diversity is recorded in the atomic mechanism of softening during static and explosive forming. In the case of static straining, the softening passes through the rest and recrystallization stages. In explosive forming with a high degree of work hardening, the appearance of new grains is delayed and a second relaxation process with a much higher activation energy is observed. L. Gordnenko. TITLE: Explosive strengthening of Armco-iron

SOURCE: Fizika metallov i metallovedeniye, v. 21, no. 1, 1966, 92-96

TOPIC TAGS: Armco iron, metal hardening, explosive strengthening

ABSTRACT: Some specific features of explosion-induced strain hardening in Armco-iron have been studied. Twinning was found to have a significant strengthening effect. For instance, at a surface hardening of 140 HB (low explosion pressure), the microhardness of twins was 180 H_P and that of single grains, 150 H_P. At a higher surface hardness of 220 HB (high explosion pressure), the microhardness of twins was 260—270 H_P. The effect of explosive strengthening depends also on grain size and the condition of the metal. While in the case of coarse grains the surface hardness did not exceed 180—190 HB, the hardness of fine-grained metal reached 220—230 HB. In specimens annealed at 1000°C and brine quenched, explosive loading increased the hardness to 280—290 HB, compared to 227—232 HB obtained in cold-rolled specimens. Softening (with Card 1/2

L 15771-66

ACC NR: AP6005141

2

annealing at 400—600°C) of explosively strengthened metal differs significantly from that of conventionally strain-hardened metal. While in the latter a relatively short period of relaxation is followed by recrystallization,⁶ in the former the recrystallization is delayed and a second relaxation period takes place. Unlike conventional strain hardening, the residual plastic deformation⁷ does not increase the hardness in explosive strengthening and even can lower it owing probably to annealing by the heat generated by deformation. TOPIC TAGS: millisecond meter, discrete millisecond meter

TRANSLATION: A circuit is described and errors analyzed of a transistorized millisecond meter. The instrument comprises a reference-pulse generator, a starting unit, and a pulse counter. The starting unit turns on the counter at the beginning of the measurand time interval and turns off the counter by the end of the interval. The counter comprises a series of count-start triggers. Either lamps showing the states of triggers by the end of counting period or a pointer instrument is used as an indicator. The instrument error is analyzed. In the author's view, the fundamental error is due to the discrete counting, i. e., to the repetition period of the reference pulses.

Title : The Periods of Setting and Winter Resistance of the
Fruit Buds in Stone Fruits Species.

Orig Pub : Mr. Pledobovoshch. opyt. selkss. st. v st. Kryukov,
1956, 1, 105-143

Abstract : A study of the differentiation of the fruit buds was
conducted on the trees of apricot, peach, sweet cherry,
sour cherry and plum. According to the characteristics
of the growth of the trees two types were identified:
with the monocyclic growth - sweet cherry, sour cherry and
plum (*Prunus domestica*). The following were identified

Card 1/4

USSR/Cultivated Plants - Fruits. Berries.

Ars Jour : Acta Zool. - Biol., No 10, 1953, 44304

with polycyclic growth - peach, apricot, plum (*Prunus avulata*), plum-prune, plum (*P. salicina*). The emergence of the premature shoots of the secondary growth from the first group does not correspond to their biology. The secondary shoots of the sweet cherry and of the plum (*P. domestica*) mature readily and are injured by the winter desiccation. In the varieties of the second group the processes of the maturing of the lignin proceed very rapidly and by the end of the fall period the secondary shoots are usually sufficiently mature and are not injured by winter. The summer pruning is an important means in the complex of caring for the monocyclic fruit varieties. There are three phases in the process of formation of fruit buds in the stone varieties: the first from the closure of the formation of the stipule and in the leaf until its transition into the summer quiescent period. The second

Card 2/4

- 143 -

M.

Abs Jour : Ref Zhur - Biol., N 10, 1953, 44304

phase - from the time of flowering individualizes along the cone of growth the appearance of petals in the forming flowers. The third - post-formation of anthers, of the core and of the stigma. The faster the growth of the shoot and the better its nutrition, the earlier and within shorter length of time does the second phase of the setting of the fruit buds take place. The periods of the passing on to the second phase of the formation of fruit buds on vigorously growing shoots, especially on the shoots of peach and apricot, depend on the intensity of the growth during this period. The buds of the peach, apricot and sweet cherry pass into the third phase after a certain interval of time thereby explaining the complete absence of the secondary flowering in these varieties. The cherry and plum buds pass directly into the third phase after the end of the second phase. Therefore, very frequently in fall, the flower buds are completely formed. The third phase continues

Card 5/4

USSR. Cell for Variants - Fruits. Leningrad.

N.

Ans. Journ. : 1953, No 10, 1953, 44304

From October to December-January. The later the fruit buds appear, the more they are winter-resistant at the end of the winter. In summer the appearance of secondary buds is stimulated and the setting of the fruit buds is delayed to September-October. This method is recommended under the conditions of the Krasnodarskaya O. lost for apricot, plum (*Prunus divaricata* a) and plum (*Prunus divaricata*) - prunus (*Prunus*). ... I.K. Fortunatov

TITLE: Saturated vapor pressure of $S_2O_5Cl_2$

PERIODICAL: Zhurnal prikladnoy khimii, v. 33, no. 6, 1960,
1272 - 1280

TEXT: The present work aimed at determining the effect of temperature on the vapor pressure of $S_2O_5Cl_2$. To do this and to determine the effect of chemical disassociation of $S_2O_5Cl_2$ on the vapor pressure, the author employed three different methods: dynamic, static and flow. Experimental work is then described. The $S_2O_5Cl_2$ obtained appeared as a transparent, colorless, volatile liquid. It contained 99.7 - 99.9 % of $S_2O_5Cl_2$; HSO_3Cl was determined by a special method and found to be present only as slight traces or to be completely absent. Determination of the vapor pressure by the

Card 1/3 X

dynamic method is then explained, done on the Swietoslawski apparatus. A full diagrammatic presentation is given of the apparatus used. The inert gas employed was nitrogen which was completely free from traces of moisture. The rate of gas flow was 1.4 - 1.8 l/hour. The ellutriating vapor of $S_2O_5Cl_2$ was condensed in liquid nitrogen traps. The quantity of $S_2O_5Cl_2$ was determined roughly by weighing the traps and accurately by a volumetric method which determined the total acidity and concentration of chloride ions. During experimental work employing the flow method and dynamic method special precautions were taken to prevent atmospheric moisture entering the equipment. The author give a full account of the static method and the procedure used. The results obtained on the vapor pressure of $S_2O_5Cl_2$ using the three methods were: Dynamic temperature of 44.9 - 151°C; flow method - temperature interval 26.1, 40 - 60°C and static - temperature interval 22.5 - 150.4°C show a good practical agreement. The best results are obtained in the case of the dynamic method in the lower temperature range. It

was established that $S_2O_5Cl_2$ undergoes partial chemical decomposition at much lower temperatures than suggested by earlier investigations. A production method is suggested for the production of high purity $S_2O_5Cl_2$ completely free from moisture (fractional crystallization in vacuum) and from HCO_3Cl . parabolic reflector (focal length - 365 mm). An optical-acoustical radiation receiver with a receiving surface of Ø 6 mm and a window of cesium iodide was employed as an indicator. Signals were received by the modulation method. The longwave boundary of received radiation ($\lambda \sim 13.5$) was practically limited by absorption in atmospheric water vapors and carbon dioxide gas. The test method is explained in detail in the article. Data were obtained on the effective temperature of the Moon at full moon and during lunation at a variation of the phase angle by 150°. The effective temperature of the Moon, averaged over the disk, at full moon is 380° K and the temperature at lunar midnight, found by an extrapolation of experimental results, is 120-130°K. The phase variations of temperature are compared with theoretical data, indicating, in particular, that the value of the parameter $(k\rho c)^{-1/2}$ lies within the limits of 250-400. "In conclusion the authors wish to express their gratitude to V. D. Krotikov for his valuable advice and discussion of the results, and also to A. P. Naumov and M. B. AUTHOR: Ryadov, V. Ya.; Furashov, N. I.; Sharonov, G. A.

TITLE: Measurement of air transparency at the 0.87 mm wavelength

SOURCE: Radiotekhnika i elektronika, v. 9, no. 6, 1964, 943-949

TOPIC TAGS: air transparency, solar radiation, submillimeter radiation, water vapor absorption, radiation attenuation, radio meteorology

ABSTRACT: Theoretical investigations of the transparency of the earth's atmosphere in the submillimeter band and spectroscopic studies indicate that the attenuation of submillimeter radiation is, for all practical purposes, due to absorption by the water vapor in the air. Using a radioastronomical method and solar radiation data, the authors of this article measured the coefficient of absorption in the transparency region centered about an average wavelength of 0.87 mm. The method is based on the relative measurements of the air-attenuated solar radiation at various zenith angles. The measurements were taken

Card 1 / 3

ACCESSION NR: AP4040908

in the Pamir Mountains at 3,860 m above sea level using apparatus described in a previous article by C. I. Averkov and others (Astronomicheskiy Zhurnal, 1964, 41, 3, 541). The mean specific vertical absorption at that elevation was 1.8 db per g/m^3 of water vapor. When the ground-level humidity characteristic of the region and season was $0.5-3 \text{ g/m}^3$, the total vertical absorption in the 0.87 mm transparent region, in the 0.9 cm^{-1} signal band, was $0.9-5.4 \text{ db}$. The experimental value of the coefficient of absorption was 10.4 db/km , which is 1.9 times higher than the theoretical value. The 40% discrepancy between these experimental and theoretical values can be attributed to the lack of experimental data for the vertical distribution of humidity. The minimum coefficient of absorption was computed to be $= 8.5 \text{ db/cm}$. The authors express gratitude to S. A. Zhevakin for his valuable advice and discussions. TITLE:

Indication of Infra-red Radiation By Means of Thermal
Signal-frequency Transducers

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika,
Vol 2, Nr 5, pp 697 - 702 (USSR)

ABSTRACT:

The transducers considered operate at wavelengths of the order of 10μ and consist of a blackened film which is heated by the measured radiation on one side; the other side, is detected by a sensitive photoresistor. The problem consists of determining the threshold sensitivity of such a transducer. A signal of frequency ω is applied to the input 1 of the system. It passes through a high-frequency filter 2 and enters into the chamber 3, which is filled with a substance which absorbs the energy of the electromagnetic radiation and converts it into heat. The substance is heated to a temperature T and radiates a signal of

Card 1/4

68643

S/141/59/002/05/004/026

E192/E382

Indication of Infra-rad Radiation by Means of Thermal Signal-frequency Transducers

frequency Ω ; this passes through the filter 4 and then, via a transmission line 5, is applied to the indicator 6. In the steady state, the energy balance of the system is described by:

$$P_c = \frac{\alpha_2}{\alpha_1} [P_\omega(T) - P_\omega(T_o)] + \frac{1}{\alpha_1} [P(T) + P_\Omega(T) - P_\Omega(T_o')] \quad (1)$$

where P_c is the input signal power,

$P_\omega(T)$ is the radiation flux from the substance in the chamber,

$P_\omega(T_o)$ is the radiation flux of the background,

$P(T)$ is the power transferred from the chamber,

$P_\Omega(T)$ is the power at the output of the transducer,

$P_\Omega(T_o')$ is the power at frequency Ω applied to the indicator and

α_1 and α_2 are the absorption coefficients of the chamber.

Card 2/4

66643

S/141/59/002/05/004/026

E192/E582

Indication of Infra-red Radiation by Means of Thermal Signal-frequency Transducers

If the chamber is cooled to a temperature T'_o , Eq (1) can be written as Eq (2). Since the temperature difference $\Delta T = T - T'_o$ is small, Eq (2) can also be written as Eq (3), where $M(T'_o)$ is defined by Eq (4).

The time constant of the thermal indicator is defined by Eq (5), where c_o is the overall thermal capacity of the substance. Consequently, Eq (3) can be written as Eq (6). The signal-to-noise ratio at the output of the filter 4 is defined by Eq (8). If the modulation method of the reception of weak signal is employed, the signal-to-noise ratio can be expressed by Eq (9), where G is the noise factor and N is the so-called modulation gain which is defined by Eq (10). The symbol Δf in Eq (10) represents the bandwidth of the filter 4 and ΔF is the bandwidth of the low-frequency filter of the indicator 6. Assuming that ΔT has a minimum value when Eq (9) is equal to unity, the minimum distinguishable

Card 3/4

68643

S/141/59/002/05/004/026

E192/E382

Indication of Infra-red Radiation by Means of Thermal Signal-frequency Transducers

temperature can be expressed by Eq (12). From this it follows that the threshold sensitivity of the transducer is defined by Eq (13). For the case of $\Omega > \omega$, it is found, on the basis of Eq (13), that the threshold sensitivity is of the order of 0.75×10^{-10} W. This value is comparable with the sensitivity of other types of transducers. For the case of $\Omega < \omega$, it is found that the threshold sensitivity is defined by Eq (22). The authors thank A.I. Khvostova for participation in the preparation of the article. There are 1 figure and 5 references, 1 of which is English and 4 are Soviet.

TITLE: Atmospheric absorption of e-m waves in the 0.76—1.15 mm band

SOURCE: IVUZ. Radiofizika, v. 9, no. 5, 1966, 859-866

TOPIC TAGS: absorption spectrum, radio wave absorption, millimeter wave propagation, ATMOSPHERIC PROPERTY

ABSTRACT: Ground-level atmospheric absorption of wavelengths in the 0.67—1.15 mm range is described. The tests supplement those of the author and others on absorption in the submillimeter range, and are claimed to be the most precise published to date. In an otherwise clear atmosphere water vapor is the main absorptive agent in this frequency band, hence the data are presented as functions of absolute humidity over the transmission path. The transmitter (Fig. 1) used a backward-wave amplifier feeding a 900 mm diameter parabolic reflector via an elliptical subreflector 100 mm in diameter. In order to correct for wide changes in transmitter power when tuning over the test band, the transmitted signal was sampled (Z_3 , Fig. 1) and compared to a standard IR source to generate corrective feedback. Other steps to standardize power included frequent polishing of the reflector surfaces and recoating. Transmitter power was on the order of a few milliwatts, and was mechanically chopped at

at 10 cps. Wavelength was measured by a Boltzman interferometer. Reception was by means of a radiometer, also using a 900 mm parabola and a type OAP-2 pneumatic indicator. To reveal possible systematic errors, two techniques were used: 1) transmission over fixed distances at varying humidity, and 2) transmission over various distances at fixed humidity. Paths were over water, and ranged from 350 m to 1.89 km. Transmitter and receiver were both 12.5 m above ground which, with a 5' beamwidth, minimized reflections from the water surface. Results

Card 2/3

ACC NR: AP6033279

from both methods agreed well enough to conclude that no systematic error was detectable. Fig. 2 shows the spectral results, corrected to standard atmospheric conditions. It is seen that absorption, particularly in the 0.87 mm window, is somewhat greater than predicted by theory. Orig. art. has: 4 figures. [WA-12]

TITLE: The width of the absorption line of water vapor at $\lambda = 0.92$ mm

SOURCE: IVUZ. Radiofizika, v. 9, no. 6, 1966, 1073-1077

TOPIC TAGS: spectral line, spectral absorptivity, line width, absorption coefficient, absorption line, WATER VAPOR

ABSTRACT: The absorption coefficient of the water vapor of the atmosphere was measured in the range of the resonance of the spectral line $1/\lambda_{ij} = 10.86 \text{ cm}^{-1}$, which corresponds to the rotational transition $4_0 - 5_{-4}$. Recent measurements have shown that the absorption coefficients obtained experimentally differ from those obtained by calculations (given by Benedict and Kaplan). Therefore, the absorption lines corresponding to the $4_0 - 5_{-4}$ ($\lambda_{ij} = 0.92$ mm) transition were measured. The measurements were conducted over the water's surface by a method in which the humidity was varied over the 1350 m between the transmitter and receiver. A source of monochromatic radiation and a radiometer with a thermal indicator were used in the measurements. The absorption was measured at an average temperature of 20°C and an average pressure of 760 mm Hg. During the measurements the temperature was constant within $\pm 8^\circ\text{C}$ and the pressure within ± 10 mm Hg. Under the assumption that the dipole moment of the

UDC: 621.371.166.2

Card 1/2

ACC NR: AP7001209

transition is 1.84×10^{-18} CGSE, i.e., is equal to the value of the dipole moment of the H₂O molecule, averaged over all states, the obtained halfwidth of the line was $\Delta v/c = 0.101 \pm 0.009 \text{ cm}^{-1}$. This value is 19% higher than that obtained by Benedict and Kaplan. Orig. art. has: 3 formulas and 1 figure. [WA-72]

The effect of gossypol on the unaccountable loss of oil in the production. V. Ryadovg., *Mashobino Zhurnal Peda* 13, No. 6, 25-41 (1887).—The discrepancy of about 1% between the contents of oil in the seed meals as delid, by the extn. with CH_3O and petr. ether and the production yields of oil was traced to the difference between the contents of gossypol in the solvents (0.6-0.77%) and in the pressed oil (0.007%). Since the press cakes contain no gossypol, it is evident that during the roasting process the gossypol in seed meal becomes insol. by combining with the aluminum products. Only 0.3% oil is wasted by mech. losses in the production. To obtain related values the crushed seeds before testing should be dried at 100° for 2 hrs. Chas. Blane.

containing 50 gm/liter La, 50 gm/liter (Nd+Pr) and 10 gr/liter Y(pH = 4-5). As shown in Fig. 1 on the Enclosure, the optimum electrolysis potential is +3.0 volts. The maximum dissociation currents as a function of Ce(III) ion concentration (see Fig. 2 on the Enclosure) were found to be linear over a wide operating range. Orig. art. has: 3 figures and 1 table.

TITLE: The effect of the hardening temperature on the mechanical properties of manganese steel

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 15, 1961, 16, abstract 15A104 ("Tr. Khar'kovsk. politekhn. in-ta", 1960, v. 15, 111-114)

TEXT: Investigations revealed that alloying manganese steel (2% Mn) with niobium (0.15 - 0.3% Nb) increases δ_b and δ_s . The hardening temperature of steel with Nb is recommended to be 1,000°C. Hardening from this temperature with subsequent high tempering results in the optimum combination of strength and ductility. ✓

AUTHOR: Ryaguzov, V. G.

TITLE: Follow-up system with a thyratron power amplifier

SOURCE: IVUZ. Elektromekhanika, no. 1, 1964, 99-103

TOPIC TAGS: computer, amplifier, power amplifier, thyratron power amplifier, followup system, thyratron followup system

ABSTRACT: A follow-up system in which the well-known amplitude-phase method of thyratron control by means of a differential peak transformer is used is briefly described. A 6N8M electron-tube modulator controls the differential transformer, and a passive integro-differential circuit in the feedback stabilizes the follow-up system. BD-404 contactless selsyns are used as sensors. Simplified circuit diagrams of the follow-up system and its thyratron control are supplied. The following advantages are claimed: (1) Low static error;

Card 1/2

ACCESSION NR: AP4018292

(2) Smooth operation with sensor speeds within 0.5-28 degrees/sec; (3) Low dynamic error; (4) Stable operation with a gap introduced into the receiving mechanism. The follow-up system is recommended for computers and its "principles can be used in power drives." Orig. art. has: 3 figures.

TITLE: Equations of a disturbed heat exchanger and schemes for their simulation

SOURCE: IVUZ. Elektromekhanika, no. 1, 1966, 40-51

TOPIC TAGS: heat exchanger, partial differential equation, computer simulation

ABSTRACT: The electronic simulator is based on the approximate equations of a uniflow (once-through) constant-pressure steam generator in which the counter-flow motion of media in both circuits is used. A high-temperature high-pressure single-phase liquid flows in the primary circuit. The secondary circuit can be subdivided into three zones: (1) The economizer zone: from feed-water temperature to saturation temperature; (2) The evaporation zone; and (3) The super-

UDC: 536.27 + 621.565

Card 1/2

L 06990-67

ACC NR: AP6017162

heater zone: from saturation temperature to output-steam temperature. Equations of the heat balance in the primary circuit and of the heat and mass balances in the secondary circuit are set up. These equations are partial differential equations with variable coefficients whose solution on an electronic simulator would require many computing units. As only one independent variable can be handled in the available simulator, all but one partial derivatives are replaced with increment ratios. This technique permits using an analog simulator for solving transient-regime heat-exchange equations. Orig. art. has: 6 figures and 40 formulas.
